Present value (PV) is the current worth of a future sum of money or stream of cash flows given a specified rate of return. Future cash flows are discounted at the discount rate, and the higher the discount rate, the lower the present value of the future cash flows.

Risk, return, and the time value of money are central inputs in distilling the cost of capital. An NPV calculation will look at the forecasts for future cash flows, and as to the general definition and considerations involved in the cost of capital.

Net Present Value Defined.

Let’s examine each step of NPV in order. The formula is: \( \text{NPV} = \sum \left( \frac{\text{After-Tax Cash Flow}}{(1+r)^t} \right) - \text{Initial Investment} \). Broken down.

The internal rate of return (IRR) is a method of calculating rate of return. The term internal refers to the period in which the majority of the problem is defined (e.g., using months if most of the cash flows are expected in the next few months).

Both the internal rate of return and the net present value can be applied to liabilities as well as investments. is calculated using the period in which the majority of the cash flows are expected to occur.
